- □ Good
We offer — Many solutions

Whatever your challenge, we have a solution
Four main factors determine the properties of a molded part. They also limit the manufacturing processes that can be used:
- Type and length of fibers
- Plastic matrix
- Component geometry
- Production volume

Manufacturing expertise in fiber composites
For many years, KraussMaffei has been working with widely varying processes for manufacturing parts made of fiber-reinforced plastic (FRP). These processes have traditionally evolved from injection molding technology and reaction technology (PU). Today our process portfolio ranges from injection molding of components with short-glass-fiber reinforcement to high-strength, lightweight parts with a complex mesh structure in a reactive matrix.

We set the highest priority on manufacturing processes that are automation-capable.

Process expertise and engineering know-how
We start working on the component requirements right from the project and development phase, instead of dealing only with the process itself. We support you throughout the entire project phase: from the initial idea, to the start of production, all the way to the first series components.

Our engineers have unique expertise from all fields of plastics processing. We can also supply molds as well as systems for post-mold processing, finishing, and component testing. With this wide product and service portfolio, KraussMaffei is the ideal partner for your entire development and implementation process.

Check out what KraussMaffei can offer you!
Discover the whole wide world of fiber-reinforced plastics with our processes and machinery in this brochure and put our expertise to the test.

Consult us about your next project; it is a challenge we will welcome! And you can be sure of our support from start to finish.
**Your partner over the entire value-adding chain**

Machine overview

Whatever you aim to achieve in plastics or rubber processing, KraussMaffei is your partner. We are the only company with mastery of the three most important machine technologies, and we link our expertise in these fields to develop new processes and systems.

Ready for any challenge
KraussMaffei's Injection Molding Machinery Division engineers and supplies systems, including automation solutions, for standard applications and for almost all processing variants. Our main markets are in the automotive, packaging, electrical, electronics, medical technology and consumer goods industries.

In Reaction Process Machinery, we engineer and supply machines and systems for processing polyurethanes and other reactive materials. Tooling Technologies supplies a complete range of molds and tooling, cutters and routers. Our customer base is wide, with a focus on the automotive, construction and the white appliances industries.

In the field of Extrusion Technology we cover compounding, extrusion of pipes, profiles, films and sheets, physical foaming, and the manufacturing of technical rubber products and semi-finished tire products. Products from the company’s range – from single extruders to complete extrusion lines – are used in industries as diverse as chemicals, automotive, construction, furniture, packaging and pharmaceuticals.

Lightweight construction and fiber composite technology – Our core competency

KraussMaffei is not just a machinery and systems expert in automated manufacturing of lightweight fiber composite components, but also has cross-process technological expertise over the whole value-adding chain.

We are the only company in the world to offer the best manufacturing technology for the part specifications and target quantities of our customers while providing them with expert support throughout the entire manufacturing process.

Benefits of fiber composite technology at a glance:
- Wide ranging fields of application
- Highest component requirements and property profiles
- Wide range of manufacturing processes
Mobility, energy, environment, lightweight – Our solutions are used across the board

Fiber composite solutions
Injection molding with short or long-fiber-reinforced pellets

Familiar standard
Injection molding with short fibers (IM-SGF)

Thermoplastics are often reinforced with short fibers, usually glass fibers, to increase the stiffness and strength of the molded part. The ready-compounded pellets normally have a fiber content of 15 to 50 percent by weight. Materials used in series production of technical parts have a fiber content of 60 percent and more.

The highly abrasive ends of the glass fibers stick out of the half-melted pellets and aggravate the wear on the plasticizing unit. KraussMaffei plasticizing units have a level of wear protection to match the application. This ensures that process parameters remain constant over a longer service life.

Processing of long-fiber-reinforced pellets (IM-LGF)
The use of long-fiber-reinforced thermoplastic pellets (LFT) significantly improves the mechanical properties of components. The length of the fibers corresponds to the pellet length; fiber lengths of 12 and 25 mm are common. Long-fiber-reinforced thermoplastics cost much more to manufacture than short-fiber pellets, so it is important to preserve the long fibers by using a gentle processing technique and thereby take advantage of their reinforcing properties.

Special screws and compression molding
Specially designed screws in the plasticizing unit reduce shearing and prevent fibers from breaking as well as excessive wear. Injection compression molding and customized mold geometry for ribs, radii and, above all, the hot runner system reduce damage to fibers during filling and shaping.

Impact-resistant components with LFT
Adding short glass fibers to a resin matrix produces parts with high rigidity, strong enough to take higher loads. The same can be achieved with long fibers and a low fiber content, meaning a lower weight. LFTs with higher fiber content are preferred for non-visible semi-structural components, such as front ends and instrument panel supports. These components need high impact resistance in order to function despite impacts and vibrations. LFT components inevitably have fewer oriented fibers, because the long fibers tend to block each other.

Multidisciplinary know-how for fiber-reinforced pellets
We combine our expertise in material processing, compounding of plastics, and injection molding to deliver impressive complete solutions. To supply our customers with solutions tailored to their formulations and processes over the whole process chain, we apply our extensive knowledge of processes from all essential application areas and our design skills as an experienced mechanical engineering company. We are experts when it comes to integrating reinforcement materials and fillers, such as glass fibers, talc, carbon fibers, calcium carbonate, barium sulfate, etc.

Your benefits:
- Short cycle times enable fully automated production of higher quantities
- Improved mechanical properties and high stiffness compared to unfilled materials
- Can be combined with almost any other injection molding variant
Process | Injection molding of short and long glass fiber-reinforced thermoplastics

Description | Many thermoplastics can be reinforced with short glass fibers. The ready-compounded pellets normally have a fiber content of 15 to 50 percent by weight. They are processed in standard injection molding machines where the plasticizing unit has additional wear protection.

By contrast, LFT with fiber/pellet lengths of 12-25 mm needs to be processed in machines with specially adapted screw geometries and usually also with an injection compounding process that avoids damaging the long fibers.

Features | 1. Fully-automated standard injection molding machine, slightly modified
2. Familiar processing method
3. Wide choice of materials from many different suppliers

Typical applications | Seat shells, instrument panel supports, door modules, technical under-hood parts

Typical annual volumes | 300,000 to 600,000 items

Products of KraussMaffei machines

| Component | Gearbox support |
| Material | PA 66 with 50 percent short glass fibers |
| Technology | Standard injection molding with wear-protected plasticizing unit |
| Benefits | – Withstands high and oscillating mechanical loads; highly temperature resistant
– Greater design freedom than for metals; acoustic damping
– Weighs 50 percent less than an equivalent metal part |

| Component | Door module and interior trim of door |
| Material | Decor: TPO film with flexible foam Substrate: PP with 10 percent long glass fibers |
| Technology | Injection molding with a fiber-friendly screw; Single-stage process (DecoForm), as TPO film is directly backfoamed |
| Benefits | Highly cost-competitive, because it combines visible parts and multifunctional parts with enhanced mechanical specifications |
Fiber composite solutions
IMC – Injection Molding Compounder

IMC combines compounding and injection molding – Unbeatably inexpensive for large series production

The matrix polymer is first plasticized and mixed with additives in a corotating twin-screw extruder.

The reinforcing fibers are fed into the extruder, wetted with the molten thermoplastic, which naturally shortens them, and transferred to an injection piston. During the brief injection and holding pressure phase, the compound, which is produced continuously, is collected in a melt buffer. The continuous melt process guarantees constant good material quality.

Lower production costs with better properties
Direct compounding/injection with the IMC saves energy and material costs (0.3 to 1.0 €/kg cheaper than processing LFT pellets). As a result, it has widely replaced LFT in manufacturing semi-structural components. The mechanical properties of finished parts are also better because the process is less destructive to the fibers. The fibers are only processed once (instead of twice if pellets are used) and they are fed into the melt in the direction of processing. Process steps such as pelletizing, cooling and remelting are omitted.

Automated and flexible for series production
The IMC process can be highly automated. Together with other key benefits, this makes direct compounding the process of choice for producing big runs of fiber composite parts. The integrated control ensures that the formulation and the material quality are constant and that the process is fully documented. Changes to the formulation are simple, so that the process can be adapted flexibly to meet different part specifications. The IMC system is just one example of productive interdisciplinary collaboration at KraussMaffei – it successfully merges injection molding know-how with expertise in compounding and extrusion.

Your benefits:
– Short cycle times enable fully automated production of higher quantities
– Long fibers for better material properties and high stiffness
– Lower material costs
**Process**

**Description**
The IMC—Injection Molding Compounder—combines continuous compounding, typical of extrusion systems, with injection molding, which is a discontinuous process. This way long-fiber-reinforced thermoplastic components can be produced with better properties and at a lower cost than using pellets.

**Features**
1. Highly automated process
2. Flexible adaptation to changing requirements
3. Compounding using low-cost standard raw materials

**Typical applications**
Frontend carriers, transmission elements, front partitions, battery wells

**Typical annual volumes**
300,000 to 600,000 items

---

**Products of KraussMaffei machines**

</table>
| Benefits        | – Lower part weight through acoustic-defined wall thickness reduction  
|                 | – Higher filler content and good homogeneity  
|                 | – No trimming waste |
Thermoplastic structural components with functional integration

To further improve the strength of fiber-reinforced injection molded parts, KraussMaffei combines injection molding with thermoforming of composite sheets.

Fabric made of endless fiber in a thermoplastic matrix is heated, shaped in the injection mold and then back injected. This process can be used to add ribs for extra stiffness and to integrate other functions.

**Fast and highly automated**

Cycle times are similar to typical values for injection molding (around 60 seconds) and are chiefly determined by the cooling time in the mold. The process can be seamlessly integrated into an injection molding operation. In other words, FiberForm is ideal for manufacturing lightweight structural parts for large series production.

**Highly-automated manufacturing cells**

Like standard injection molding, FiberForm can be easily automated. The outcome is compact, fully-automated manufacturing cells.

**Versatile process**

Like injection molding, FiberForm can be combined with almost all special manufacturing processes. This opens up infinite potential for functional integration and part design.

**Your benefits:**
- Parts are demolded with their final contour, no post-processing required
- Short cycle times, typical of injection molding processes
- Fully automated manufacturing process

1. Pick up insert
2. Preheat insert
3. Transfer to mold
4. Thermoforming
5. Back injection
6. Remove from mold

**Fully automated processing of BMC/SMC molding compounds**

Thanks to their very low viscosity, thermosets are especially suitable for wetting fibers to produce fiber-reinforced plastics (FRP). Due to their high temperature resistance, thermoset FRP parts are still regularly used as substitutes for metals.

Sheet Molding Compound (SMC) and Bulk Molding Compound (BMC) are used for very stiff, precision parts, which are often painted. The broad range of use from low temperatures up to 180 °C enables a diverse field of applications as well as in-line painting of Class A surfaces.

**The raw material that’s a little different**

The doughy polyester or vinylester-based resins are reinforced with glass fiber. BMC is reinforced with short glass fibers, SMC with long glass fiber (25–50 mm). The compounds are supplied ready-to-use.

**Unique feed system – reliable injection molding process**

The doughy material is removed from its packaging and placed directly, without interrupting the production cycle, into the feed hopper of an injection molding machine. The rotating action of the hopper and the feed screw transports the material into the heated plasticizing unit. After injection, the precisely metered thermoset cures in the hot mold to produce the finished part.

**Your benefits:**

- Precision feeding thanks to the controlled stuffing pressure and uniform processing conditions
- Refilling processes without interrupting the cycle
- Outstanding material homogenization and fiber-friendly processing
### PolySet – Continuous injection molding of polyester dough molding compounds (BMC, SMC)

**Description**
PolySet – Process for polyester dough molding compounds that are not free flowing, for small to medium component sizes.

**Features**
1. Unique feed method for continuous material transport of the polyester dough molding compounds, regardless of the material’s form and consistency
2. Robust construction, long service life even processing highly abrasive materials
3. Special, material-specific machine portfolio for thermosets

**Typical applications**
Valve covers, headlamp reflectors, oil sumps, ashtrays

**Typical annual volumes**
200,000 to 300,000 items

Perfect surfaces with low wall thicknesses with highly reactive PU systems

In R-RIM, short fibers (glass, carbon, wollastonite) or fillers are added to the polyol before processing. The PU mixture is poured into the closed mold, where it cures quickly.

R-RIM on wear-resistant machines
The filler is mixed into one of the PU components, in general the polyol, in a special premixing station. A piston metering machine is used. In the mixing head, the filled polyol is mixed – intensively and at high speed – with the isocyanate during the shot and the PU mix is injected into the closed mold. R-RIM is the only process for PU fiber composite applications where the reinforcing material is contained directly in one component. To reduce the abrasion risk, the mixing head and the metering system for the filled component are treated for wear resistance.

Volume parts for inline painting
The R-RIM process produces parts with excellent material properties. It has proven a cost-competitive process for large series production. Using fast-reacting PU systems, cycle times can be as short as 90 seconds. Adding short fibers to the resin improves the stiffness, dimensional stability under heat and the thermal expansion coefficient of the finished parts, making them ideal for car bodywork elements. Stable, reliable production systems and minimal post-mold processing meet the requirements of the automotive industry.

Your benefits:
– Dimensional stability and inherent stiffness even at high temperatures
– Good paintability, even at temperatures up to 180 °C, inline painting is possible
– Low investment in molds and tooling

Low component weight with high bending stiffness

In SCS processes, layers composed of fiber mats and honeycomb cores are sprayed with unreinforced PU, inserted into a mold and pressed into shape.

**Thin layers on lightweight honeycomb cores**
This further development of LFI/honeycomb technology reduces the thickness and weight of the cover layers to further optimize the lightweight construction. First a sandwich structure is made by putting the fiber mats on both sides of the honeycomb core. Then the sandwich is sprayed with PU on both sides. Next the frame holding the sprayed sandwich is inserted into the mold, which is then shut. During pressing, the fiber mats are saturated with PU and adhere to the fiber core as the PU cures.

**Core plus outer layers produce extremely light, stiff parts**
With substrate and core layers matched as regards material properties and part geometry, it is possible to produce extremely light parts which are also very rigid. The SCS process has huge potential to produce lightweight parts and this potential is far from being exhausted. Fiber mats containing continuous fibers and thicker PU layers sharply increase the mechanical strength of the load-bearing edge layers.

**Decorated surface on both sides**
In the applications presented here, the decorative elements are positioned in both mold halves before pressing. The SCS process produces parts with ready-to-use surfaces.

**Your benefits:**
- Optimized lightweight construction for moderate-strength parts
- Low operating costs, low material consumption
- High-quality finish surfaces possible on both sides

1. Assemble the sandwich
2. Spray a PU layer on both sides
3. Press component into shape while PU cures
4. Finished part ready for next process

Low mold costs, automated material pouring by means of robots, many variants – ideal for short runs

Fiber Composite Spraying is a very flexible process for short-run production. By applying individual PU layers, it is possible to produce composite parts that are optimally adapted to their respective application.

Each different layer can be made completely or partially of compact or foamed material, with or without fiber reinforcement. This way nearly any wall thickness can be created. Only one mold-half is required for manufacturing. Because of the lower initial investment, FCS is especially suitable for small series production.

Modular system concept
In the simplest case, it’s possible to use just a 2C spray mixing head with the appropriate metering machine. An optional H₂O metering unit makes it possible to further vary the PU system between compact or foamed. A 4-component mixing head allows even more variability. Fibers are always metered coaxially into the PU spray jet, which enables the fibers to be optimally wetted with PU. The glass fibers can come from rovings and be cut to length during the process, or ready-cut glass can be used. In most applications, fiber length is between 5 and 20 mm and the fiber content in the part can be up to 25 percent.

Stiff sandwich parts for a minimal investment
The FCS process is ideal for high-strength, very rigid, large-format, visible parts required in small quantities. The process uses only a simple negative mold without a mold carrier. Although this is an automated, highly repeatable process, the tooling and investment costs are minimal. The surfaces of the medium-sized or large parts can be finished with a thermoformed film or using IMP (In Mold Painting).

Your benefits:
- Cost-effective for short-run production, even for very large components
- First-class surfaces through simple process combinations, for example, with In Mold Painting (IMP)
- High stiffness and strength thanks to multiple layers
**Process**

**FCS – Fiber Composite Spraying**

**Description**

Spraying a layer consisting of fibers and a PU system into an open mold. It is air-cured.

**Features**

1. Variable, application-specific layer structure (filled, unfilled and foamed layers)
2. Spraying into the negative mold – simple, lower-cost molds
3. Fiber content up to about 25 percent, fiber lengths between 5 and 20 mm

**Typical applications**

Fenders, engine covers, large-format hoods and covers for machines

**Typical annual volumes**

5,000 to 10,000 items

Lightweight components with high impact resistance not just in the automotive sector

In the LFI (Long Fiber Injection) process, continuous fibers from a roving are fed into a cutter, where they are chopped to length and separated into the individual filaments by a blower. Immediately after the cutter, the fibers are wetted with the PU mixture from the mixing head.

The fiber/PU compound is poured into the open mold, under robot control, as a sharply focused spray cone. Once the mold is filled, it closes and the compound cures.

Specific localized properties
The fiber lengths can vary between 12.5 and 100 mm. During the discharge, the fiber content can continuously change between 0 and 50 percent, with 50 percent being the limit for good impregnation. Today the most commonly used PU systems are either compact or foamed. This means that the property profile of LFI is comparable to that of SMC.

Stable and very light
Long fibers, freedom to design part geometries, and the variety of PU systems enable a broad range of applications. LFI parts can vary from a small trim part for a car interior to a large structural part with a Class A visible surface. Since this is a PU process where mold cavity pressures are < 10 bar, LFI can be used at the same time to produce a high-strength sandwich element with a honeycomb structure as the core layer. Typical products here are rear trays for cars or very large partitions.

Your benefits:
- First-class surfaces produced by simple process combinations (IMP, film)
- High strength values (fiber content up to 50 percent, fiber lengths 12.5–100 mm)
- Moderate mold and machine costs

Very light, very strong
High-performance lightweight components

In HP-RTM (High-Pressure Resin Transfer Molding), the first step is building up a fiber preform.

This consists of layers of carbon or glass fibers; the fabric layers can be stitched or fixed together with a binder to keep them correctly aligned. How the layers are put together depends on the loads the structural component will later be subjected to; preforming could be used. This preform is placed in the mold, the mold is then closed and evacuated. Then a very low-viscosity, reactive epoxy resin, polyurethane or cast polyamide is injected into the cavity at high pressure ensuring that each individual fiber is wetted and that there are no air gaps.

The C-RTM (Compression Resin Transfer Molding) process differs from the HP-RTM (high-pressure RTM) process essentially by having the resin mixture fed into the mold when it is slightly open instead of closed. Thus the mold is not completely closed during the feeding. Consequently, the preform is already partially saturated by resin. The feeding is followed by a compression stroke, which presses the resin through the preform, causing it to become completely saturated.

Outstanding strength
The HP-RTM process produces extremely light structural parts that meet the highest specifications, complying for instance with car crash test standards. This process is already established in the aerospace industry, mechanical engineering, and the automotive industry. The HP-RTM process can produce parts with fiber content up to 50 percent.

High pressure at heat
Generally, PU, epoxy and cast polyamide can be used as the matrix material. KraussMaffei offers the right machine for each of these materials. If PU systems are processed at temperatures up to a maximum of 80 °C, the epoxy resins or cast polyamides used in HP-RTM require machines modified to process materials at temperatures up to 120 °C.

Your benefits:
- Lightweight parts to meet highest specifications, around 50 percent lighter than steel
- Paintable components for visible applications
- Can be fully-automated and is suitable for series production (from preform production to post-mold processing)
### Process

| HP-RTM – High-Pressure Resin Transfer Molding |
| C-RTM – Compression Resin Transfer Molding |

#### Description

**HP-RTM:** Fiber mats or fabric are preformed and then positioned in the mold. The mold closes, the resin is injected and cures in the closed mold.

**C-RTM:** Fiber mats or fabric are positioned in the mold. Resin is added in the slightly open mold and the reaction occurs in the closed mold.

#### Features

1. Virtually unidirectional reinforcement with endless fiber
2. High-pressure technology allows the use of fast-curing systems
3. High fiber contents of up to 50 percent

#### Typical applications

Structural components, sidewall panels, floor pans, front-end carriers, crash boxes, carbon-fiber design components

#### Typical annual volumes

10,000 to 120,000 items

---

Structural components with and made of recycled material

The wet molding process provides another alternative to the series production of fiber-reinforced lightweight components.

This involves fixing a pile of fiber mats made of carbon or glass fibers in place as an unworked piece, unformed and flat, outside of the mold. Then the reactive resin is thinly applied to the fiber pile in layers. As soon as the fibers are covered with resin, the fiber pile with the layer of resin is transported into the mold and compressed there by closing the mold. This is where the fiber mats are preformed and the component is cured.

**Manufacturing with recycled fiber mats**

Recycled fiber mats can be used in the wet molding process. The manufacturing process for the fiber mats can reuse materials such as the waste product from cutting fiber mats made of continuous fibers. In the process, the individual fibers are coated with a binder and formed into mats again. However, the fibers are no longer aligned, but instead statically distributed. The flow resistance would be extremely high for impregnation in a closed mold, which is why the resin is added outside of the mold.

**Short cycles and fast reaction times**

Whatever the material being processed, KraussMaffei machines are ideally suited for processing fast-reacting systems; the mixing heads are all engineered for high-pressure processing. This leads to a very good mix of fast curing resin systems. The mixing head is self-cleaning. We also offer an extra module to meter in an internal release agent directly at the mixing head. This ensures an overall process that is fully-automated and cost-effective.

**Your benefits:**

- Lightweight parts to meet highest specifications, around 50 percent lighter than steel
- Can be fully-automated and is suitable for series production

---

**1. Intermediate cut from a roll**
2. Handling the intermediate
3. Transfer to the discharge station
4. Application of a thin coating in layers (resin)
5. Transfer of pile to RTM station
6. Compression of the resin/pile, impregnating via compression, creating a vacuum (optional)
7. Curing
8. Part removal

Movement in three dimensions
Description
Resin is added to an unformed fiber pile or fabric mats outside of the mold. Transport of the fiber pile into a mold where the component is preformed.

Features
1. Processability of, for example, recycled material
2. Lower compression tonnages are required because of the far lower cavity pressure
   Manufacturing of 2 D to 2.5 D components

Typical applications
10,000 to 120,000 items

Generate foam structures in lightweight injection molding

**MuCell™:** Blowing agent reduces weight and improves precision molding. MuCell™ technology is a physical process for foaming of thermoplastics. It uses nitrogen or carbon dioxide as blowing agents. For this purpose, the gas is transformed into a supercritical fluid (SCF), fed into the plastic melt towards the front of the barrel and mixed with the melt.

During the injection process, the SCF expands and produces a component with a microcellular foam structure (<100 µm) in the core and a solid outer layer.

Even with low amounts of blowing agent, the MuCell™ process offers clear benefits:
- Weight reduction from lower density
- Higher dimensional stability and fewer sink marks as the blowing agent expands
- Shorter cycle times thanks to a higher injection speed and elimination of the holding pressure time
- Lower clamping forces due to reduced material viscosity and elimination of the holding pressure

Using MuCell™ in conjunction with a foam stroke can result in very high degrees of foaming with a high bending stiffness and uniform wall thicknesses.

**Your benefits:**
- Reduced component weight
- Shorter cycle time
- Smaller clamping forces
High-quality painted surfaces straight from the mold – Painting integrated into the manufacturing process

Colors galore in a straightforward process: In Mold Painting. In the IMP process, a paint and/or primer system (barrier coat) is sprayed into an open mold cavity either manually or by a robot. The spray system can consist of one or two components.

The IMP technique allows for flexible color management and fully meets most product specifications. The substrate material is either injected or sprayed, e.g. using LFI or FCS technology, into the mold after the paint layer. The combined system then reacts in the closed mold to give a resilient, uniform surface finish.

**Your benefits:**
- Process with one or two components
- Flexible color management
- Durable and uniform surface
System and processing expertise from idea to production

Partnerships are often launched during purely informative discussions on all sorts of occasions.

The first idea
The very first sketches and ideas define some of the parameters for the production process. Even at this early stage, our specialists are on hand to support our partners with advice and help them work out appropriate and flexible solutions. Feasibility studies also take into account possible production processes and downstream operations.

Process delivers specific component properties
As a component takes on shape and size, reliable material data is essential in order to design for different load cases. Especially for fiber composite structures with anisotropic characteristics, process trials are important for validating the production process and component properties.

Prototyping and fine-tuning
In our TechCenter we have facilities for producing prototypes and preproduction parts. This learning phase also shows up further optimization opportunities for the production process.

Solutions for series production
Once the component and the production process have been agreed, we will work with you to develop the best production solution. The degree of automation, postprocessing and coordination of downstream operations are all important considerations. We will then quote for a solution optimized with respect to capital investment and unit manufacturing costs.

Project and implementation phase
Our experienced project engineers are on hand to give you support, from planning and implementation to on-site production start-up, and will even assume responsibility for the project management if desired.

Production support
At the start of production (SOP) and during the start-up phase, highly-skilled experts support you with their knowledge of processes and machinery. This ensures a smooth start of production and simultaneously trains the personnel in your plant.

Service
After the production start we continue as your reliable partner.

Your benefits:
- Single-source system solutions
- Support of your project as a partner
- Individualized handling of projects and solutions
TechCenter for lightweight construction and fiber composite technologies

New ideas for components often also require new or adapted production processes. For an idea to be successful, the associated production process has to prove itself in practice.

Machine and process expertise
With its unique combination of injection molding and reaction machinery, the KraussMaffei TechCenter makes it easy to test, optimize or advance your processes using experimental carriers or initial prototypes under real-world conditions. A team of process developers, application engineers and technicians is at your service in the TechCenter. Thanks to different perspectives, the close cooperation between experts in the fields of injection molding technology and reaction technology produce synergies and new ideas from which you will profit.

Watch this space
Our TechCenter for injection molding and reaction technology covers an area of 4000 square meters and is populated with over 25 machines and systems for various production processes.

Open and yet discreet
Mutual trust is a must when it comes to new processes and developments. To ensure the necessary confidentiality and to protect our customers’ know-how we reserve separate production areas for each customer during trials and tests.

Your benefits:
- Test development processes as experimental carriers or prototypes
- Interdisciplinary fields for new ideas
- Test options for various manufacturing processes
Your visions take form with our PU and compression molds

The combination of best possible process and mold technologies brings your vision of a structural component into shape.

For working with duroplastics and intermediates, KraussMaffei can supply the complete manufacturing system – the processing machinery including the mold technology – from its own resources and ensure that the principal components interact perfectly. A bonus of dealing with just one partner for the whole system is streamlined project completion that saves you time and reduces hassle.

PU mold technology – fine-tuned for each specific application
KraussMaffei molds can be adapted to a large number of different processes. This opens up new options for producing structural components. Each mold is specially engineered for a specific application and fine-tuned to production requirements:
- Temperature control matched to process requirements
- Extra wear protection where necessary, for instance, if you’re processing abrasive materials
- Optimal ejector concept for damage-free part demolding
- Seal technology to suit the product
- Optionally with integrated trimming solution

Tooling technology for forming and shaping
Fiber composites are often processed in the form of intermediates. KraussMaffei’s modular mold concepts can be configured to mold any specific type of intermediate. This mold technology enables us to offer turnkey system solutions to manufacture a huge range of products – as prototypes and for series applications:
- For glass fiber-reinforced structural components
- For parts made of natural fiber composites
- For LFI processes
- For a wide spectrum of foaming and casting processes

Your benefits:
- Turnkey system solutions for prototypes and series applications
- Wide variety of PU molds for various processes
- Optimum mold design for your production requirements
Powerful systems for trimming fiber composite components

In mass production, stable and fully automated processes are very important for parts to be manufactured cost-effectively. KraussMaffei offers you comprehensive solutions for trimming your products.

Our solutions for trimming composite fiber components range from engineering to prototyping all the way to finished series solutions. KraussMaffei relies exclusively on the use of robot solutions for this. These enable good access to the component and efficient processing with up to three milling spindles. In-house-fabricated product holders ensure high cut precision and low variation in manufacturing tolerances.

The milling of fiber composite components, especially CFRP components, presupposes a lot of experience in selecting a milling tool. This is where the entire cost-effectiveness of the process is defined. For years, KraussMaffei has been designing and delivering punching and milling solutions for the plastics processing industry and has experience from various tasks, including milling multiple thousands of vehicle components for a renowned automaker.

Therefore we are capable of determining what the ideal mold is for your application. By means of conducting our routine process simulation, we determine the cycle time to be expected. Then it is easy to predict the manufacturing costs.

Our robot cells are not only flexible, but also highly mobile. Conversion of the cell in manufacturing can be accomplished in a few minutes and usually requires only slight adaptations to the program or none at all.

The systems are programmed via offline systems, which enable trimming trajectories to be created quickly and efficiently as well as adaptations with precision down to 1/100 mm. Taking into consideration the task description, a pure teaching of these trajectories is very labor and time-intensive.

Your benefits:
- Proven technology
- Individual, process-neutral advice
- The most cost-effective solution for every task
TechCenter for lightweight construction and fiber composite technologies

Lab tests are major milestones for developing new components until they are ready for series production. KraussMaffei provides in-house component testing and can apply the findings gained from this to optimize manufacturing cells and PU molds flexibly and immediately, without losing time.

A system partnership with KraussMaffei shortens your communication paths and ensures significant time savings on the way from design study to volume production.

ISO-accredited test center
Our test lab is accredited in accordance with DIN EN ISO/IEC 17025:2005 and is specifically equipped to test components and assemblies for automotive interiors and exteriors. We have the facilities and the in-house expertise to test safety-critical chassis and structural components, electronic control devices and pyrotechnical safety restraint systems. On request and after intensive consultation, we will also develop customized testing programs.

Extract from the KraussMaffei testing portfolio
Vibration & shock: Electrodynamic vibration testing equipment enables us to simulate all mechanical loads as defined by national and international standards or to OEM specifications. If required, temperature and climate profiles can be imposed on the vibration.
Climate, sunshine, heat and cold: our test lab is equipped to simulate extreme weather and temperature conditions with precise repeatability and assess their impact on test samples.
Temperature shock: The temperature shock test provokes the mechanical stresses which can occur when components made of materials with different thermal expansion behavior are exposed to extreme temperatures, which can ultimately destroy the component.
Corrosion: the corrosive properties of salt spray atmospheres and condensate can damage materials and surfaces. Especially in the automotive segment, corrosion resistance is a significant sign of quality and safety.

Your benefits:
- Customized testing program
- No lost time, since the results flow directly into optimizing manufacturing cells and PU molds
- Various options for testing the components
Further information which might also interest you

Are you looking for more information about HP-RTM processes? KraussMaffei offers you turnkey production lines for series production.

**Everything from a single source:**
Together with our partners, we are able to cover all stages of the process chain – from unwinding the semi-finished textile product (e.g. CFRP fabric) through to final processing of the finished fiber composite component – as turnkey solutions incorporating a high level of system expertise.

**You can also learn about:**
- PU metering machines for processing reactive systems, particularly polyurethane
- Our mixing heads for the various processes and technologies
- Versatile PU mold carriers and systems

You can find our brochures and flyers on other topics online at: www.kraussmaffei.com. On request, we would also be happy to send you information and technical data for our products free of charge.
KraussMaffei
A strong brand in a unique global group

Cross-technology system and process solutions
Whether in Injection Molding, Reaction Process Machinery or Automation – the KraussMaffei brand stands for pioneering and cross-technology system and process solutions in plastics processing worldwide. For decades, our expertise, innovative ability and passionate commitment to plastics engineering have been your competitive edge. As a cross-industry system provider, we offer you modular and standardized systems as well as solutions customized to your needs.

There for you around the world
With our worldwide sales and service network, we offer our international customers an excellent basis for a successful business relationship. Due to the close proximity to our customers, we are able to answer your individual inquiries very quickly. We work out the best possible technical and economical solution for your product and production requirements together with you. Test our machine technology for your applications and let our experts put together an individualized service package for you.

Individualized service
Our employees from customer service, application technology and service help you with your questions and needs on every topic dealing with machines, systems and processes – around the globe, quickly and with a high level of expertise. We have developed an extensive customized service spectrum with our lifecycle design, which accompanies you throughout the entire lifecycle of your machines and systems. Take advantage of the personal interaction and flexibility we offer in our practically oriented seminars. We carry out customer-specific trainings either at your location or at our sales and service locations.

KraussMaffei Group
Comprehensive expertise

Unique selling proposition Technology
The KraussMaffei Group is the only provider in the world to possess the essential machine technologies for plastics and rubber processing with its KraussMaffei, KraussMaffei Berstorff and Netstal brands: Injection Molding Machinery, Automation, Reaction Process Machinery and Extrusion Technology.

The group is represented internationally with more than 30 subsidiaries and over ten production plants as well as about 570 commercial and service partners. This is what makes us your highly skilled and integrated partner. Use our comprehensive and unique expertise in the industry.

You can find additional information at: www.kraussmaffeigroup.com

The KraussMaffei Group has a global presence. Countries with subsidiaries are marked in dark blue. In the white-colored regions, the Group is represented by over 570 sales and service partners.
Fiber composite solutions for advanced lightweight components

In many sectors, component specifications are being ratcheted continuously upward. Typically, customers want higher mechanical strength and lighter weight.

KraussMaffei is not just a machinery and systems expert, but also possesses expertise in the entire value-adding chain for automated manufacturing of lightweight fiber composite components, regardless of the process.

We are the only company in the world to offer the best manufacturing technology for the part specifications and target quantities of our customers.

You will find KraussMaffei the ideal partner as you work to transform your visions into reality.
